# REAL ALGEBRAIC GEOMETRY LECTURE NOTES (06: 05/11/09 - BEARBEITET 14/11/2018)

#### SALMA KUHLMANN

## Contents

1.	Counting roots in an interval	1
2.	Bounding the roots	2
3.	Changes of sign	4

Let R be a real closed field (for all this lecture).

## 1. Counting roots in an interval

**Definition 1.1.** Let  $f(x) \in R[x], a \in R$ ,

$$f(\mathbf{x}) = (\mathbf{x} - a)^m h(\mathbf{x})$$

with  $m \in \mathbb{N}$ ,  $m \ge 1$  and  $h(a) \ne 0$  (i.e. (x - a) is not a factor of h(x)). We say that m is the **multiplicity** (*Vielfachheit*) of f at a.

**Corollary 1.2.** (Generalized Intermediate Value Theorem: Verstärkung Zwischenwertsatz). Let  $f(x) \in R[x]$ ;  $a, b \in R$ , a < b, f(a)f(b) < 0 (i.e. f(a) < 0 < f(b) or f(b) < 0 < f(a)). Then the number of roots of f(x) counting multiplicities in the interval  $]a,b[\subseteq R]$  is odd (in particular, f has a root in ]a,b[).

*Proof.* By Corollary 3.1 of 5th lecture (3/11/09), we can write

$$f(\mathbf{x}) = \prod_{i=1}^{n} (\mathbf{x} - c_i)^{m_i} g(\mathbf{x})$$

with g(x) = dq(x), where  $d \in R$  is the leading coefficient of f(x) and q(x) is the product of the irreducible quadratic factors of f(x).

Note that g(x) has constant sign on R (i.e.  $g(r) > 0 \ \forall r \in R$  or  $g(r) < 0 \ \forall r \in R$ ). Without loss of generality, we can suppose d = 1 (and so g(x) is positive everywhere).

Set  $\forall i = 1, \ldots, n$ 

$$\begin{cases} L_i(\mathbf{x}) := (\mathbf{x} - c_i)^{m_i} \\ l_i(\mathbf{x}) := \mathbf{x} - c_i. \end{cases}$$

If  $l_i(x)$  changes sign in ]a, b[ we must have  $l_i(a) < 0 < l_i(b)$ . Note that  $L_i(x)$  changes sign in ]a, b[ if and only if  $l_i(x)$  does and  $m_i$  is odd.

In particular if  $L_i(x)$  changes sign we must have  $L_i(a) < 0 < L_i(b)$  as well.

Let us count the number of distinct  $i \in \{1, ..., n\}$  for which  $L_i(a) < 0 < L_i(b)$ . We claim that this number must be odd. If not, we get an even number of i such that  $L_i(a)L_i(b) < 0$ , so their product would be positive, in contradiction with the fact that f(a)f(b) < 0.

Set

$$|\{i \in \{1, \dots, n\} : L_i(a) < 0 < L_i(b)\}| = M \ge 1$$
 odd.

Say these are  $L_1, \ldots, L_M$ . So the total number of roots of f in ]a, b[ counting multiplicity is

$$\sum := m_1 + \dots + m_M.$$

Since  $m_i$  is odd  $\forall i = 1, ..., M$  and M is odd, it follows that  $\sum$  is odd as well.

2. Bounding the roots

Corollary 2.1. Let  $f(x) \in R[x]$ ,  $f(x) = dx^m + d_{m-1}x^{m-1} + \dots + d_0, d \neq 0$ . Set

$$D := 1 + \sum_{i=m-1}^{0} \left| \frac{d_i}{d} \right| \in R.$$

Then

- (i)  $a \in R$ ,  $f(a) = 0 \Rightarrow |a| < D$ ; (i.e. f has no root in  $] - \infty, -D] \cup [D + \infty[$ )
- (ii)  $y \in [D, +\infty[ \Rightarrow \operatorname{sign}(f(y)) = \operatorname{sign}(d);$
- (iii)  $y \in ]-\infty, -D[ \Rightarrow \operatorname{sign}(f(y)) = (-1)^m \operatorname{sign}(d).$

*Proof.* Wlog assume  $\exists i$  such that  $d_i \neq 0$ .

(i) For every  $i=0,\ldots,m-1$  set  $b_i:=\frac{d_i}{d}$  and compute for  $|y|\geqslant D$ :

$$f(y) = dy^{m} (1 + b_{m-1}y^{-1} + \dots + b_0y^{-m}).$$

Now

$$|b_{m-1}y^{-1} + \dots + b_0y^{-m}| \le (|b_{m-1}| + \dots + |b_0|)D^{-1} < 1.$$

- (ii) If  $y \ge D$  then  $f(y) = d \prod (y a_i)^{m_i} q(y)$  where  $\deg(q)$  is even and  $y a_i > 0$ .
- (iii) If  $y \leq -D$  then  $(y a_i)^{m_i} < 0$  if and only if  $m_i$  is odd. Moreover m is odd if and only if  $\sum m_i$  is odd.

**Corollary 2.2.** (Rolle's Satz) Let  $f(x) \in R[x]$ ,  $a < b \in R$  such that f(a) = f(b). Then there is  $c \in R$ , a < c < b such that f'(c) = 0.

*Proof.* We can suppose f(a) = f(b) = 0 (otherwise if  $f(a) = f(b) = k \neq 0$ , we can consider the polynomial (f - k)(x)).

We can also assume that f(x) has no root in a, b. So

$$f(\mathbf{x}) = (\mathbf{x} - a)^m (\mathbf{x} - b)^n g(\mathbf{x}),$$

where g(x) has no root in [a, b], and by Corollary 1.2 (IVT) g(x) has constant sign in [a, b]. Compute

$$f'(x) = (x - a)^{m-1}(x - b)^{n-1}g_1(x),$$

where

$$g_1(x) := m(x - b)g(x) + n(x - a)g(x) + (x - a)(x - b)g'(x).$$

Therefore

$$g_1(a) = m(a - b)g(a)$$
  

$$g_1(b) = n(b - a)g(b).$$

Since  $g_1(a)g_1(b) < 0$ , by the Intermediate Value Theorem (1.2)  $g_1(x)$  has a root in [a, b[ and so does f'(x).

**Corollary 2.3.** (Mittelwertsatz: Mean Value Theorem) Let  $f(x) \in R[x]$ ,  $a < b \in R$ . Then there is  $c \in R$ , a < c < b such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Proof. We can apply Rolle's Satz to

$$F(x) := f(x) - (x - a)\frac{f(b) - f(a)}{b - a},$$

since 
$$F(a) = F(b)$$
.

**Corollary 2.4.** (Monotonicity Theorem). Let  $f(x) \in R[x]$ ,  $a < b \in R$ . If f' is positive (respectively negative) on ]a,b[, then f is strictly increasing (respectively strictly decreasing) on [a,b].

*Proof.* If  $a \leq a_1 < b_1 \leq b$ , by the Mean Value Theorem there is some  $c \in R$ ,  $a_1 < c < b_1$  such that

$$f'(c) = \frac{f(b_1) - f(a_1)}{b_1 - a_1}.$$

## 4

## 3. Changes of sign

## Definition 3.1.

- (i) Let  $(c_1, \ldots, c_n)$  a finite sequence in R. An index  $i \in \{1, \ldots, n\}$  is a **change of sign** (*Vorzeichenwechsel*) if  $c_i c_{i+1} < 0$ .
- (ii) Let  $(c_1, \ldots, c_n)$  a finite sequence in R. After we have removed all zero's by the sequence, we define

$$Var(c_1,...,c_n) := |\{i \in \{1,...,n\} : i \text{ is a change of sign}\}|$$
$$= |\{i \in \{1,...,n\} : c_i c_{i+1} < 0\}|.$$

**Theorem 3.2.** (Lemma von Descartes) Let  $f(x) = a_n x^n + \cdots + a_0 \in R[x]$ ,  $a_n \neq 0$ . Then

$$|\{a \in R : a > 0 \text{ and } f(a) = 0\}| \le \operatorname{Var}(a_n, \dots, a_1, a_0).$$

*Proof.* By induction on  $n = \deg(f)$ . The case n = 1 is obvious, so suppose n > 1. Wlog assume that  $a_0 \neq 0$ .

Let r > 0 be the smallest positive index such that  $a_r \neq 0$ . By induction applied to

$$f'(\mathbf{x}) = na_n \mathbf{x}^{n-1} + \dots + ra_r \mathbf{x}^{r-1},$$

we know that there are  $Var(na_n, ..., ra_r) = Var(a_n, ..., a_r)$  many positive roots of f'. Set c := the smallest such positive root of f' (by convention  $c := +\infty$  if none exists)

Apply Rolle's Theorem: f has at most  $1 + Var(a_n, \ldots, a_r)$  positive roots.

- **Case 1.** If the number of positive roots of f is strictly less than  $1 + \operatorname{Var}(a_n, \ldots, a_r)$ , then the number of positive roots of f is  $\leq \operatorname{Var}(a_n, \ldots, a_r) \leq \operatorname{Var}(a_n, \ldots, a_r, a_0)$  and we are done.
- Case 2. Assume f has exactly  $1 + Var(a_n, ..., a_r)$  positive roots. We claim that in this case

$$1 + \operatorname{Var}(a_n, \dots, a_r) = \operatorname{Var}(a_n, \dots, a_r, a_0).$$

We observe that f has a root a in ]0, c[.

For 0 < x < c we have that  $sign(f'(x)) = sign(a_r) \neq 0$ , so f is strictly monotone in the interval [0, c] (Monotonicity Theorem). So

$$a_r > 0 \implies a_0 = f(0) < f(a) = 0 \implies a_0 < 0,$$
  
 $a_r < 0 \implies a_0 = f(0) > f(a) = 0 \implies a_0 > 0.$ 

In both cases  $a_0a_r < 0$  and the claim is established.

**Corollary 3.3.** Let  $f(x) \in R[x]$  a polynomial with m monomials. Then f has at most 2m-1 roots in R.

*Proof.* Consider f(x) and f(-x). By previous Theorem they have both at most m-1 strictly positive roots in R. So f(x) has at most 2m-2 non-zero roots and therefore at most 2m-1 roots in R.
